

# COMPUTER SKILLS

## LESSON 12

---

Valeria Cardellini  
cardellini@ing.uniroma2.it  
A.Y. 2015/16

# Objectives of this lesson

We'll discuss

- Functions that return more than one value
- Functions that accomplish a task without returning values
- Functions that return values versus printing
- Passing arguments to functions

# Recall function definition (lesson 9)

Function header

```
function [output arguments] = functionname(input arg)
```

```
%
```

```
%comment describing the function
```

```
%
```

Comments area

```
    statements here; these must include putting values  
    in all the output arguments listed in the  
    header
```

```
end
```

Function body

Function and end are reserved words and are mandatory

# Objectives of this lesson

We'll discuss

- Functions that return more than one value
- Functions that accomplish a task without returning values
- Functions that return values versus printing
- Passing arguments to functions

# Functions that return more than one value

```
function [area, circum] = areacirc(rad)
    % areacirc returns the area and
    % the circumference of a circle
    % Format: areacirc(radius)

    area = pi * rad .* rad;
    circum = 2 * pi * rad;
end
```

```
>> help areacirc
areacirc returns the area and
the circumference of a circle
Format: areacirc(radius)
```

# Functions that return more than one value (cont'd)

- `function [area, circum] = areacirc(rad)`

```
>> [a, c]=areacirc(4)
a =
    50.2655
c =
    25.1327
```

```
>> areacirc(4)
ans =
    50.2655
```

```
>> a=areacirc(4)
a =
    50.2655
```

```
>> [~, c]=areacirc(4)
c =
    25.1327
```

# Passing a vector as input

- `function [area, circum] = areacirc(rad)`

```
>> [a, c]=areacirc(1:4)
```

```
a =
```

```
    3.1416    12.5664    28.2743    50.2655
```

```
c =
```

```
    6.2832    12.5664    18.8496    25.1327
```

```
>> [a, c]=areacirc(1:4)
```

is equivalent to

```
>> [a, c]=areacirc([1,2,3,4])
```

## Alternative way to process an input vector

- Create a script with the following MATLAB code

```
for i=1:4  
    [a(i), c(i)]=areacirc(i);  
end
```

- After running the script, in the workspace there will be

```
>> a
```

```
a =
```

```
    3.1416    12.5664    28.2743    50.2655
```

```
>> c
```

```
c =
```

```
    6.2832    12.5664    18.8496    25.1327
```

## Alternative way to process an input vector

- Create a script with the following MATLAB code

```
for i=1:4  
    [a(i), c(i)]=areacirc(i);  
end
```

- After running the script, in the workspace

```
>> a
```

```
a =
```

```
    3.1416    12.5664    28.2743    50.2655
```

```
>> c
```

```
c =
```

```
    6.2832    12.5664    18.8496    25.1327
```

Easier and more efficient to write  
>> [a, c]=areacirc(1:4)

# How to call a function

- From the Command Windows
- From a script
  - Let's write a script to call `areacirc.m`

```
% This script prompts the user for the radius of a circle,  
% calls a function to calculate and returns both the area  
% and the circumference, and prints the results. To keep  
% the script simple, we ignore units and error-checking
```

```
radius = input('Please enter the radius of the circle: ');  
[area, circ] = areacirc(radius);  
fprintf('For a circle with a radius of %.1f,\n', radius)  
fprintf('the area is %.1f and the circumference is %.1f\n', ...  
    area, circ)
```

## Example: `perimarea.m`

- Write a function that calculates and returns the perimeter and area of a rectangle
  - Input: length and width
  - Output: perimeter and area
- Call the function from a M-script (`calcareaperim.m`)

# calcareaperim.m

```
% Prompt the user for the length and width of a rectangle,  
% call a function to calculate and return the perimeter  
% and area, and print the result.
```

```
length = input('Please enter the length of the rectangle: ');  
width = input('Please enter the width of the rectangle: ');  
[perim, area] = perimarea(length, width);  
fprintf('For a rectangle with length of %.1f ', length)  
fprintf(' and width of %.1f,\nthe perimeter is %.1f,', width,  
perim)  
fprintf(' and the area is %.1f\n', area)
```

```
>> calcareaperim  
Please enter the length of the rectangle: 10  
Please enter the width of the rectangle: 3  
For a rectangle with length of 10.0 and a width of 3.0,  
the perimeter is 26.0, and the area is 30.0
```

# perimarea.m

```
function [ perim, area ] = perimarea( length, width )  
%  
%Compute the perimeter and area of a rectangle  
%  
    perim = 2*(length + width);  
    area = length * width;  
end
```

# Let's call `perimarea.m` from cmd

```
>> [p, a]=perimarea(2,5)
p =
    14
a =
    10
```

```
>> [a, p]=perimarea([1, 5, 10],[2, 4, 6])
Error using *
Inner matrix dimensions must agree.

Error in perimarea (line 6)
    area = length * width;
```

# perimarea.m

```
function [ perim, area ] = perimarea( length, width )  
%  
%Compute the perimeter and area of a rectangle  
%  
    perim = 2*(length + width);  
    area = length * width;  
end
```

This is a matrix  
product

```
>> [a, p]=perimarea([1, 5, 10],[2, 4, 6])  
Error using *  
Inner matrix dimensions must agree.  
  
Error in perimarea (line 6)  
    area = length * width;
```

# perimarea.m

```
function [ perim, area ] = perimarea( length, width )
%
% Compute the perimeter and area of a rectangle
%
    perim=2.*(length + width);
    area = length .* width;
end
```

You must use the scalar product here

```
>> [p, a] = perimarea([1, 5, 10],[2, 4, 6])
p =
     6     18     32
a =
     2     20     60
```

## Another example (3 output args)

- Write a function that converts from seconds to hours + minutes + seconds
  - E.g. 7515 seconds = 2 hours, 5 minutes and 15 seconds
- Solution:
  - Input: total seconds (ts)
  - Output: hh, mm, ss
  - Algorithm
    - hh = integer part of  $ts/3600$ ; the remainder of  $ts/3600$  is the remaining number of seconds
    - mm = integer part of the  $(\text{remainder of } ts/3600)/60$ ; it is the remaining number of minutes
    - ss = the remainder of  $(\text{remainder of } ts/3600)/60$
- For example:  $7515 = 3600*2 + 60*5 + 15$

# breaktime.m

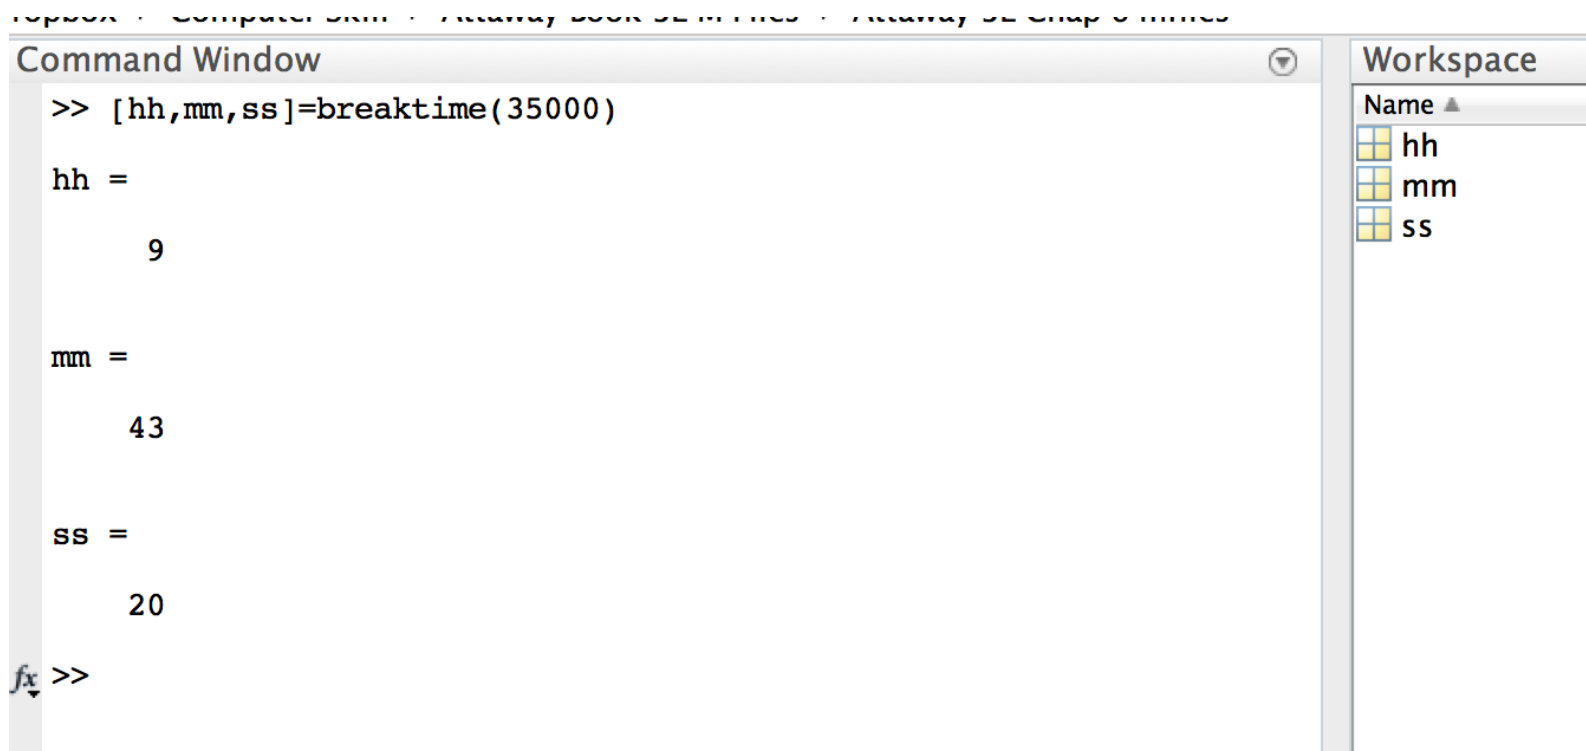

```
function [hours, minutes, secs] = breaktime(totseconds)
% breaktime breaks a total number of seconds into
% hours, minutes, and remaining seconds
% Format: breaktime(totalSeconds)
```

```
hours = floor(totseconds/3600);
remsecs = rem(totseconds, 3600);
minutes = floor(remsecs/60);
secs = rem(remsecs,60);
end
```

```
>> [hh,mm,ss]=breaktime(35000)
hh =
    9
mm =
   43
ss =
   20
```

# Variable scope: global variables

- `hh`, `mm`, `ss` are **global variables**, i.e. part of the base workspace
- `hours`, `minutes`, `secs` are **local variables** to the function `breaktime.m`

The screenshot shows the MATLAB Command Window and Workspace. The Command Window displays the execution of the function `breaktime(35000)`, which assigns values to global variables `hh`, `mm`, and `ss`. The Workspace panel on the right shows these three variables as global.

```
>> [hh,mm,ss]=breaktime(35000)
```

hh =  
9

mm =  
43

ss =  
20

fx >>

Workspace	
Name ▲	
hh	
mm	
ss	

# Variable scope: local variables

- hours, minutes, secs are local variables to the function breaktime.m

The image displays the MATLAB environment with the Command Window, Workspace, and Editor. The Command Window shows the execution of a script that defines a variable 'a' and calls the 'breaktime' function. The Workspace window shows the variables 'hours', 'minutes', 'remsecs', 'secs', and 'totseconds' with their respective values. The Editor window shows the source code of the 'breaktime' function, with a breakpoint set at line 10. The Function Call Stack shows the current function call.

**Command Window**

```
>> a=9  
  
a =  
  
9  
  
>> [hh,mm,ss]=breaktime(35000)  
10 end  
K>>
```

**Workspace**

Name	Value
hours	9
minutes	43
remsecs	2600
secs	20
totseconds	35000

Function Call Stack: breaktime, breaktime, Base

Quit Debugging

stringprompt.m breaktime.m

```
1 function [hours, minutes, secs] = breaktime(totseconds)  
2 % breaktime breaks a total number of seconds into  
3 % hours, minutes, and remaining seconds  
4 % Format: breaktime(totalSeconds)  
5  
6 hours = floor(totseconds/3600);  
7 remsecs = rem(totseconds, 3600);  
8 minutes = floor(remsecs/60);  
9 secs = rem(remsecs,60);  
10 end  
11
```

# Variable scope: local variables

- hours, minutes, secs are local variables to the function breaktime.m

The image displays the MATLAB environment with the Command Window, Workspace, and Editor. The Command Window shows the execution of a script that sets a variable 'a' to 9 and then calls the function 'breaktime(35000)'. The Workspace window shows the variable 'a' with a value of 9. The Editor window shows the source code of the 'breaktime.m' function, which calculates hours, minutes, and seconds from a total number of seconds. The function call stack is visible, showing the current function 'breaktime' and the base MATLAB environment.

**Command Window**

```
>> a=9  
  
a =  
  
9  
  
>> [hh,mm,ss]=breaktime(35000)  
10 end  
K>>
```

**Workspace**

Name	Value
a	9

- Base
- breaktime
- Base

Quit Debugging

stringprompt.m breaktime.m

```
1 function [hours, minutes, secs] = breaktime(totseconds)  
2 % breaktime breaks a total number of seconds into  
3 % hours, minutes, and remaining seconds  
4 % Format: breaktime(totalSeconds)  
5  
6 hours = floor(totseconds/3600);  
7 remsecs = rem(totseconds, 3600);  
8 minutes = floor(remsecs/60);  
9 secs = rem(remsecs,60);  
10 end  
11
```

# Objectives of this lesson

We'll discuss

- Functions that return more than one value
- Functions that accomplish a task without returning values
- Functions that return values versus printing
- Passing arguments to functions

# Functions with no output

- **function functionname(input arg)**

```
function printem(a,b)
% printem prints two numbers in a sentence
format
% Format: printem(num1, num2)

fprintf('The first number is %.1f and the
second is %.1f\n',a,b)
end
```

```
>> printem(4,5)
The first number is 4.0 and the second is
5.0
```

```
>> x=printem(4,5)
Error using printem
Too many output arguments.
```

# Objectives of this lesson

We'll discuss

- Functions that return more than one value
- Functions that accomplish a task without returning values
- **Functions that return values versus printing**
- Passing arguments to functions

# Functions that return values versus printing

```
function calccircum1(radius)
% calccircum1 displays the circumference of a circle
%   but does not return the value
% Format: calccircum1(radius)

disp(2 * pi * radius)
end
```

In this version you cannot store the result of the function in a variable ...

```
function circle_circum = calccircum2(radius)
% calccircum2 calculates and returns the
%   circumference of a circle
% Format: calccircum2(radius)

circle_circum = 2 * pi * radius;
end
```

... in this version you can

## Functions that return values versus printing (cont'd)

```
>> calccircum1(10)  
62.8319
```

```
>> x=calccircum1(10)  
Error using calccircum1  
Too many output arguments.
```

```
>> calccircum2(10)  
ans =  
62.8319
```

```
>> x=calccircum2(10)  
x =  
62.8319
```

# Good programming practice

- It is a good programming practice to **keep separate the computation and the return of a value from printing that value**. That is
  - In the function you should never print the result using **disp**, **printf**, **plot**, ...
  - In the function you should never read input from the keyboard using **input**
  - In the function you should always assign the final result of any computation to an output variable
  - The printing of results must be left to a specific script/function or to the script that invokes the function

# Objectives of this lesson

We'll discuss

- Functions that return more than one value
- Functions that accomplish a task without returning values
- Functions that return values versus printing
- **Passing arguments to functions**

# Passing argument to variables

- Argument are passed to functions using the **call-by-value** method
- It is possible to declare functions without any input parameter
  - **function [output args] = functionname()**
  - **function functionname()**

```
function printrand()  
% printrand prints one random  
number  
% Format: printrand or  
printrand()  
  
fprintf('The random # is %.2f  
\n',rand)  
end
```

```
function printrandnp  
% printrandnp prints one  
random number  
% Format: printrandnp or  
printrandnp()  
  
fprintf('The random # is %.2f  
\n',rand)  
end
```

# Another example

```
function outstr = stringprompt
% stringprompt prompts for a string and returns it
% Format stringprompt or stringprompt()

disp('When prompted, enter a string of any length.')
outstr = input('Enter the string here: ', 's');
end
```

This function returns the string entered by the user

# Homework

- Write a version of `calcareaperim.m` that considers:
  - Unit measures and input error-checking
- Do Practice 6.2
- Do Practice 6.3
- Do exercises of Chapter 6

# Assignment for Wednesday, Dec. 9th

- Study by yourself (see Chapter 6 of the book):
  - MATLAB program organization (sec. 6.2)
    - Modular programs (sec. 6.2.1)
    - Subfunctions (sec. 6.2.2)
  - Do Practice 6.4 and Practice 6.5
  - Solve the following exercises of Chapter 6
    - 2, 3, 6, 8, 10, 13, 18, 19, 24, 25
